ABSTRACT

Aims: This study retrospectively describes the demography, etiology, fracture characteristics, and hospital utilization of surgically treated mandibular condylar fractures in a tertiary referral hospital in urban China in past five years. Methods: Data of all patients who underwent surgical management between 2011 and 2015 were collected. The data of 166 patients with 208 mandibular condylar fractures included aetiology, characteristics of fracture, time, age, sex, associated injuries, and hospital utilization. These data were statistically analyzed to describe the epidemiology of mandibular condylar fracture. Results: The 166 patients mostly had unilateral mandibular condylar fractures (74.7%). Male patients (76.51%) outnumbered female patients (23.49%) in this cohort with both the gender having similar average age of 37 years. The fractures were mostly caused by fall from height (60.84%) and were located at the condylar neck (53.61%). These patients presented with other associated maxillofacial injuries (71.08%) which were mostly located at symphysis and parasymphysis (44.59%). It took 12.58 +/- 0.35 days of hospitalization for the treatment. Conclusion: Fall from height was the most prevalent cause of injury in mountainous urban China. The people at highest risk are middle-aged men. Mandibular condylar fracture are mostly located at the condylar neck and are usually associated with fracture at the symphysis and parasymphysis.

MATERIALS AND METHODS

This retrospective study included patients who underwent surgical treatment of mandibular condylar fracture between January 2011 and December 2015 in the Department of Oral and Maxillofacial Surgery at the Affiliated Stomatology Hospital of Chongqing Medical University. The patient identity, gender, age, etiology, date of injury, date of hospital admission, date of treatment, date of discharge, characteristics of the fractures, and the associated injuries were noted from clinical records.
The demographic data of age and gender were statistically analyzed to describe any significant correlation to other variables of causation, hospital utilization, or fracture characteristics. The etiology of the mandibular condylar fractures included road traffic accident, fall from height, fall at ground level, assault, and work-place injuries. The fractures were classified into three subregions according to specific landmarks and reference lines as fracture of condylar head, fracture of condylar neck, and fracture of condylar base[10]. The associated maxillofacial injuries were noted. The hospital utilization of patients was assessed as the interval between trauma and admission, between admission and surgery, and length of hospital stay.

The descriptive statistical analysis were conducted and figures generated using LibreOffice Calc spreadsheets. To analyze the relationships between multiple groups the Freeman-Halton extension of Fisher’s Exact Test and Student’s T test or ANOVA were performed. All hypothesis were verified at significance level equal to 0.05.

**RESULTS**

There were 166 patients who had presented with 208 mandibular condylar fractures that were operated in the study period between 2011 and 2015. One hundred and twenty four (74.7%) had unilateral and 42 (25.3%) had bilateral mandibular condylar fractures and this ratio was not affected statistically by age, sex, nor causation of fracture. Male patients (76.51%) clearly outnumbered female patients (23.49%) (p<0.0001). The mean age of both the genders were identical (male vs female, 37.06 +/- 1.25 years vs. 37.13 +/- 2.43 years) with age ranging between 12 years and 70 years (Figure 1).

Of the 166 patients, 47 (28.31%) had fracture of condylar head, 89 (53.61%) had fracture of condylar neck, and 30 (18.07%) had fracture of condylar base (Figure 2a). Fracture of condylar neck was seen more frequently in all age groups (Figure 2b) and both the sexes (Figure 2a).

Fall from height (60.84%), road traffic accident (17.47%), assault (7.93%), fall at ground level (7.83%), and work-related injuries (6.02%) were the causes of maxillofacial trauma (Figure 3). Fall from height was the most common cause in both male (58.27%) and female (69.23%) patients (Figure 3b) in all the age groups (Figure 3c). This was followed by road traffic accident which constituted only 17.47% of the total cases.

Forty eight (28.92%) condylar fractures were recorded without any other associated maxillofacial fractures. Seventy four (44.59%) condylar fractures were associated with fractures at mandibular symphysis and parasymphysial area. Other maxillofacial injuries associated with mandibular condylar fracture were noted at mandibular body (12.65%), denutoalveolar region (8.43%), mandibular angle (7.23%), maxilla (3.01%), and zygomatic (4.22%) (Table 1).

Of the 166 injured, 27 were admitted on the same day as the injury for the surgery; and 122 were admitted on the same week as the injury for the surgery. The mean number of days from injury to admission was 4.61 +/- 0.28 days after the admission and were discharged 7.96 +/- 0.17 days after the surgery. This time periods did not significantly vary between age-groups, genders, fracture location, nor the cause of the fracture (Figure 4).

**Figure 1. Patients’ age range from 12 to 70 years with most of the patients belonging to the age groups between 20 years and 50 years.**

**Figure 2. Location of fracture is classified into three subregions – fracture of the condylar base (18.07%), fracture of condylar head (28.32%), and fracture of condylar neck (53.61%). Fracture of neck was most prevalent in both the sexes (Figure 2a) and in all age-groups (Figure 2b).**
DISCUSSION

Epidemiological studies of fractures guide in preventive, diagnostic, and therapeutic planning. This study was conducted in Chongqing which represents urban China. One hundred and sixty-six patients who were admitted for surgical treatment for mandibular condylar fracture in a period of five years were analyzed. The male to female ratio in general population of Chongqing is 1.02 compared to 3.26 in our study population. Male predominance has been previously well established suggesting that men engage in activities of higher risk and suffer more severe mandibular trauma[1,2,6–8]. Mandibular condylar fractures were found to be more common in middle adulthood which could be assumed to be for the same reason.

Cause of mandibular injury varies in accordance with demographic and sociological factors and referral practice. Studies from different parts of the world have ranked falls[6,7], road traffic accidents[1,2,6,8], physical assaults[1,5–7], and sports injuries[9] as major causes of the mandibular fractures. Falls contributed to three fifth of the mandibular condylar fractures (60.84%) in our study population with others contributing to only a small number. Fall from height has been identified as an important cause of trauma in mountainous Chongqing with most related to their work altitude and remaining related to daily life, suicide attempts, drug abuse, alcohol, and criminal behavior[11]. Road traffic accident and physical assaults are also expected to be the major cause of fractures related to trauma in urban area. Low incidence or road traffic accidents (17.47%) and assault (7.83%) in our population suggests efficiency of modern safety majors and prevailing law and order[8].

Fracture characteristics described depend on the mechanism and severity of the injury and the patient related variables. Symphysis and parasympysis are the most common sites of injuries related to mandibular condylar fractures in different studies[7,8]. Our population which suffered mandibular condylar fracture most commonly due to falls suffered fractures most commonly at the neck and were most often related to fractures at the symphysis and parasympysis. This was not statistically related to gender or the age of the patients.

Selection bias is a limitation of this study towards more severe injuries because the patients with mandibular condylar fractures who did not require surgical management were not represented in this study.

CONCLUSIONS

This is a descriptive study of patients with mandibular condylar fracture who were treated with surgical intervention at a single tertiary referral center in mountainous urban China. These fractures were mostly due to fall from height. The middle-aged men were found to be the ones at highest risk of such injury. Most of the fractures occurred at the neck and were associated to injury at the symphysis and parasympysis. Appropriate surgical treatment done as per the protocol followed at the institute required an average of 12 days of hospital stay.

Figure 2. Location of fracture is classified into three subregions - fracture of the condylar base (18.07%), fracture of condylar head (28.32%), and fracture of condylar neck (53.61%). Fracture of neck was most prevalent in both the sexes (Figure 2a) and in all age-groups (Figure 2b).

Figure 3. Assault, fall at level (Fall L), fall from height (Fall H), road traffic accidents (RTA), and work-related injuries caused the maxillofacial injuries. It was dominated by fall from height every year in the study period (Figure 3a), in both the genders (Figure 3b), and in all age-groups (Figure 3c).

Figure 4. Mean days from injury to admission, admission to surgery, and surgery to discharge were 6.24+/−0.61 days, 4.61+/−0.28 days, and 7.98+/−0.17 days, respectively with mean days of hospitalization totaling to 12.54+/−0.35 days. When compared between different categories, there were no statistically significant difference.
